How to install Apache, PHP 7.1 and MySQL on CentOS 7.3 (LAMP)

This tutorial shows how you can install an Apache webserver on a CentOS 7 server with PHP support (mod_php) and MySQL support. LAMP is short for **L**inux, **A**pache, **M**ySQL, **P**HP.

This updated tutorial shows the installation of the latest PHP versions (7.0 and 7.1) on CentOS 7.3.

1 Preliminary Note

In this tutorial, I use the hostname `server1.example.com` with the IP `192.168.1.100`. These settings might differ for you, so you have to replace them where appropriate.

I will add the EPEL repo here to install latest phpMyAdmin as follows:

```
rpm --import /etc/pki/rpm-gpg/RPM-GPG-KEY*
yum -y install epel-release
```

To edit files on the shell, I'll install the nano editor. If you prefer vi for file editing, then skip this step.

```
yum -y install nano
```

2 Installing MySQL / MariaDB

MariaDB is a MySQL fork of the original MySQL developer Monty Widenius. MariaDB is compatible with MySQL and I've chosen to use MariaDB here instead of MySQL. Run this command to install MariaDB with yum:

```
yum -y install mariadb-server mariadb
```

Then we create the system startup links for MySQL (so that MySQL starts automatically whenever the system boots) and start the MySQL server:

```
systemctl start mariadb.service
systemctl enable mariadb.service
```

This tutorial exists for these OS versions

- [CentOS 7.3](#)
- [CentOS 7](#)
- [CentOS 6.5](#)
- [CentOS 6.2](#)
- [CentOS 6.1](#)
- [CentOS 6.4](#)

On this page

Set passwords for the MySQL root account:

```
mysql_secure_installation
```

```
[root@server1 ~]# mysql_secure_installation
/usr/bin/mysql_secure_installation: line 379: find_mysql_client: command not found
```

NOTE: RUNNING ALL PARTS OF THIS SCRIPT IS RECOMMENDED FOR ALL MariaDB
SERVERS IN PRODUCTION USE! PLEASE READ EACH STEP CAREFULLY!

In order to log into MariaDB to secure it, we'll need the current
password for the root user. If you've just installed MariaDB, and
you haven't set the root password yet, the password will be blank,
so you should just press enter here.

Enter current password for root (enter for none): **<--ENTER**
OK, successfully used password, moving on...

Setting the root password ensures that nobody can log into the MariaDB
root user without the proper authorisation.

Set root password? [Y/n]
New password: **<--yourmariadbpassword**
Re-enter new password: **<--yourmariadbpassword**
Password updated successfully!
Reloading privilege tables..
... Success!

By default, a MariaDB installation has an anonymous user, allowing anyone
to log into MariaDB without having to have a user account created for
them. This is intended only for testing, and to make the installation
go a bit smoother. You should remove them before moving into a
production environment.

Remove anonymous users? [Y/n] **<--ENTER**
... Success!

Normally, root should only be allowed to connect from 'localhost'. This
ensures that someone cannot guess at the root password from the network.

Disallow root login remotely? [Y/n] **<--ENTER**
... Success!

By default, MariaDB comes with a database named 'test' that anyone can
access. This is also intended only for testing, and should be removed
before moving into a production environment.

Remove test database and access to it? [Y/n] **<--ENTER**
- Dropping test database..
... Success!
- Removing privileges on test database..
... Success!

Reloading the privilege tables will ensure that all changes made so far
will take effect immediately.

Reload privilege tables now? [Y/n] **<--ENTER**
... Success!

Cleaning up...

All done! If you've completed all of the above steps, your MariaDB
installation should now be secure.

Thanks for using MariaDB!
[root@server1 ~]#

3 Installing Apache

CentOS 7 ships with apache 2.4. Apache is directly available as a CentOS 7 package, therefore we can install it like this:

```
yum -y install httpd
```

Here a screenshot of the installation process.

```

total
Running transaction check
Running transaction test
Transaction test succeeded
Running transaction
  Installing : apr-1.4.8-3.el7.x86_64 1/5
  Installing : apr-util-1.5.2-6.el7.x86_64 2/5
  Installing : httpd-tools-2.4.6-45.el7.centos.x86_64 3/5
  Installing : mailcap-2.1.41-2.el7.noarch 4/5
  Installing : httpd-2.4.6-45.el7.centos.x86_64 5/5
  Verifying : httpd-tools-2.4.6-45.el7.centos.x86_64 1/5
  Verifying : mailcap-2.1.41-2.el7.noarch 2/5
  Verifying : apr-1.4.8-3.el7.x86_64 3/5
  Verifying : httpd-2.4.6-45.el7.centos.x86_64 4/5
  Verifying : apr-util-1.5.2-6.el7.x86_64 5/5

Installed:
  httpd.x86_64 0:2.4.6-45.el7.centos

Dependency Installed:
  apr.x86_64 0:1.4.8-3.el7      apr-util.x86_64 0:1.5.2-6.el7      httpd-tools.x86_64 0:2.4.6-45.el7.centos      mailcap.noarch 0:2.1.41-2.el7

Complete!
[root@localhost ~]#

```

Now configure your system to start Apache at boot time...

```
systemctl start httpd.service
```

```
systemctl enable httpd.service
```

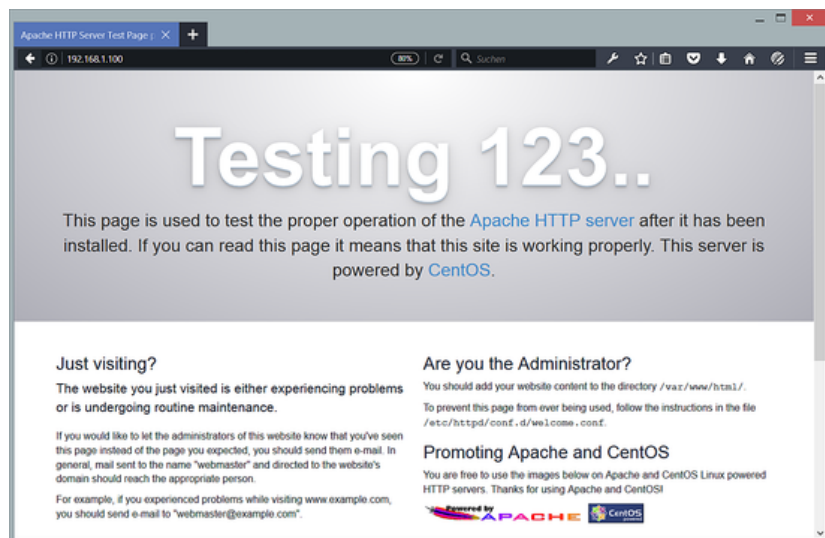

To be able to access the web server from outside, we have to open the HTTP (80) and HTTPS (443) ports in the firewall. The default firewall on CentOS is firewalld which can be configured with the firewall-cmd command.

```

firewall-cmd --permanent --zone=public --add-service=http
firewall-cmd --permanent --zone=public --add-service=https
firewall-cmd --reload

```

Now direct your browser to the IP address of your server, in my case <http://192.168.1.100>, and you should see the Apache placeholder page:

4 Installing PHP

The PHP version that ships with CentOS is quite old (PHP 5.4), therefore I will show you in this step some options to install newer PHP versions like PHP 7.0 or 7.1 from Remi repository.

Add the Remi CentOS repository.

```
rpm -Uvh http://rpms.remirepo.net/enterprise/remi-release-7.rpm
```

Install yum-utils as we need the yum-config-manager utility.

```
yum -y install yum-utils
```

and run yum update

```
yum update
```

Now you have to chose which PHP version you want to use on the server. If you like to use PHP 5.4, then proceed with the next command. To install PHP 7.0, follow the commands in chapter 4.1 and for PHP 7.1, use chapter 4.2 instead.

To install PHP 5.4, run this command:

```
yum -y install php
```

4.1 Install PHP 7.0 (optional)

We can install PHP 7.0 and the Apache PHP 7.0 module as follows:

```
yum-config-manager --enable remi-php70
```

```
yum -y install php php-opcache
```

4.2 Install PHP 7.1 (optional)

If you want to use PHP 7.1 instead, use:

```
yum-config-manager --enable remi-php71
```

```
yum -y install php php-opcache
```

In this example and in the downloadable virtual machine, I'll use PHP 7.1.

We must restart Apache to apply the changes:

```
systemctl restart httpd.service
```

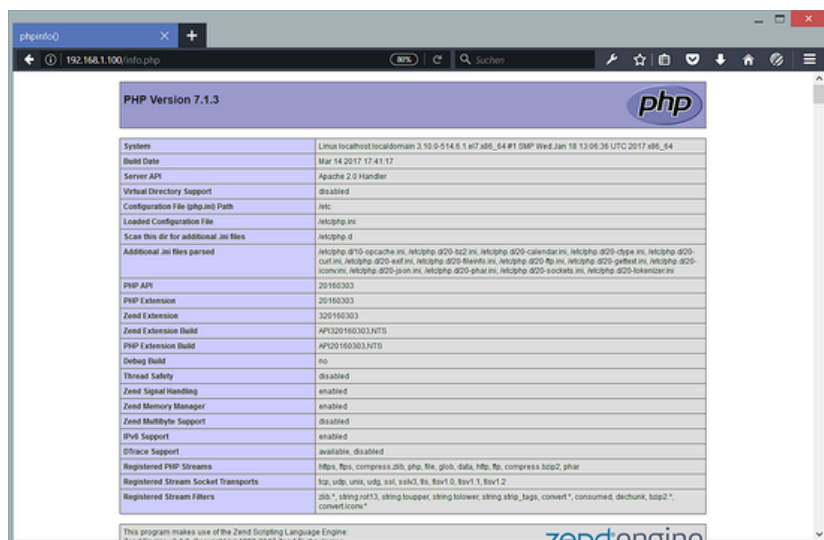

5 Testing PHP / Getting Details About Your PHP Installation

The document root of the default website is /var/www/html. We will create a small PHP file (info.php) in that directory and call it in a browser to test the PHP installation. The file will display lots of useful details about our PHP installation, such as the installed PHP version.

```
nano /var/www/html/info.php
```

```
<?php
phpinfo();
?>
```

Now we call that file in a browser (e.g. <http://192.168.1.100/info.php>):

As you see, PHP 7.1 is working, and it's working through the **Apache 2.0 Handler**, as shown in the **Server API Line**. If you scroll further down, you will see all modules that are already enabled in PHP. MySQL is not listed there which means we don't have MySQL support in PHP yet.

6 Getting MySQL Support In PHP

To get MySQL support in PHP, we can install the **php71w-mysql** package. It's a good idea to install some other PHP modules as well as you might need them for your applications. You can search for available PHP5 modules like this:

```
yum search php
```

Pick the ones you need and install them like this:

```
yum -y install php-mysql
```

In the next step I will install some common PHP modules that are required by CMS Systems like Wordpress, Joomla, and Drupal:

```
yum -y install php-gd php-ldap php-odbc php-pear php-xml php-xmlrpc php-mbstring php-soap curl curl-devel
```

Now restart Apache web server:

```
systemctl restart httpd.service
```

Now reload <http://192.168.1.100/info.php> in your browser and scroll down to the modules section again. You should now find lots of new modules like curl etc there.:

mysqli		
mysqli Support enabled		
Client API library version	mysqli 5.0.12-dev - 20150407 - lib 6399954ee62d19ed7902b6bae27b287d2ad9e \$	
Active Persistent Links	0	
Inactive Persistent Links	0	
Active Links	0	
Directive	Local Value	Master Value
mysqli.allow_local_infile	On	On
mysqli.allow_persistent	On	On
mysqli.default_host	no value	no value
mysqli.default_port	3306	3306
mysqli.default_pw	no value	no value
mysqli.default_socket	/var/lib/mysql/mysql.sock	/var/lib/mysql/mysql.sock
mysqli.default_user	no value	no value
mysqli.max_links	Unlimited	Unlimited
mysqli.max_persistent	Unlimited	Unlimited

mysqlnd		
mysqlnd enabled		
Version	mysqlnd 5.0.12-dev - 20150407 - lib 6399954ee62d19ed7902b6bae27b287d2ad9e \$	
Compression	supported	
curl SSL	supported	
extended SSL	supported	
Command buffer size	4096	

If you don't need the php info output anymore, then delete that file for security reasons.

```
rm /var/www/html/info.php
```

7 phpMyAdmin installation

phpMyAdmin is a web interface through which you can manage your MySQL databases. phpMyAdmin can now be installed as follows:

```
yum -y install phpMyAdmin
```

Now we configure phpMyAdmin. We change the Apache configuration so that phpMyAdmin allows connections not just from localhost (by commenting out the <RequireAny> stanza and adding the 'Require all granted' line):

```
nano /etc/httpd/conf.d/phpMyAdmin.conf
```

```
[...]
Alias /phpMyAdmin /usr/share/phpMyAdmin
Alias /phpmyadmin /usr/share/phpMyAdmin

<Directory /usr/share/phpMyAdmin/>
    AddDefaultCharset UTF-8

    <IfModule mod_authz_core.c>
        # Apache 2.4
        # <RequireAny>
        # Require ip 127.0.0.1
        # Require ip ::1
        # </RequireAny>
        Require all granted
    </IfModule>
    <IfModule !mod_authz_core.c>
        # Apache 2.2
        Order Deny,Allow
        Deny from All
        Allow from 127.0.0.1
        Allow from ::1
    </IfModule>
</Directory>
```

```
<Directory /usr/share/phpMyAdmin/>
    Options none
    AllowOverride Limit
    Require all granted
</Directory>

[...]
```

Next, we change the authentication in phpMyAdmin from *cookie* to *http*:

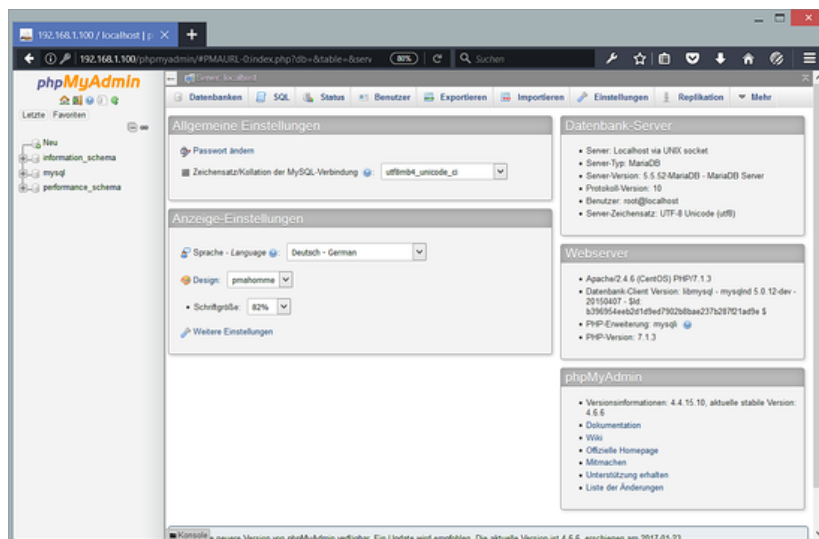

```
nano /etc/phpMyAdmin/config.inc.php
```

```
[...]
$cfg['Servers'][$i]['auth_type']      = 'http';    // Authentication method (config, http or cookie based)?
[...]
```

Restart Apache:

```
systemctl restart httpd.service
```

Afterwards, you can access phpMyAdmin under *http://192.168.1.100/phpmyadmin/*:

8 Download as virtual machine

This setup is available as virtual machine download in ova/ovf format (compatible with VMWare and Virtualbox) for howtoforge subscribers.

Login details for the VM

- The Linux root password is: howtoforge.
- RHE MySQL root password is: howtoforge

Please change both passwords on the first login.

- The IP address of the VM is 192.168.1.100

Thanks, but this doesn't work. PHP 5.4 is installed instead.

From: Tom **at:** 2017-03-29 06:25:44

[Reply](#)

I installed my server with this tutorial and I got PHP 7.1 at the end, so you must have done something wrong when you got 5.4. The guide shows to install 3 different PHP versions, use the option for the PHP version that you want to get only.
